# Growth Norms for the Teaching Strategies GOLD Assessment System 

Richard G. Lambert<br>Center for Educational Measurement and Evaluation<br>University of North Carolina at Charlotte

## Purpose

The Technical Manual for the Teaching Strategies GOLD Assessment System (Lambert, Kim, Taylor, \& McGee, 2010) contains norm tables for both raw and scale scores for each developmental domain that are based on a cross-sectional research design in the sense that they establish expected scores for three month age bands using only the fall assessment checkpoint. The expected growth for individual children can be inferred from these tables by tracking a child across the age bands as the child gets older. Given that the measure has been in use for several complete academic years since those tables were created, and users have gained more experience and training, it is important to extend the findings of that report. This report provides a supplement to those tables by tracking groups of children across a single academic year to directly observe their growth and development using a longitudinal design.

The growth norms reported in this report are based on the results of a research study conducted to accomplish five specific goals:
1.) Gather evidence that teacher ratings of child developmental status made with the Teaching Strategies GOLD assessment system can be used to track growth across time,
2.) Create norm tables for each scale score, based on a nationally representative sample, that indicate how children of different ages should be expected to score at the beginning of the academic year,
3.) Create norm tables which illustrate expected growth across the academic year for children of different ages,
4.) To establish reliability and validity evidence to support the Teaching Strategies GOLD Assessment System using the norm sample created for this research study,
5.) Create norm tables which illustrate expected scores at kindergarten entry.

## Norm Sample

A norm sample was created from the entire population of children served by teachers who used the Teaching Strategies GOLD Assessment System. Children were eligible for admission into the sample if the teachers in the program they attended had met the following criteria: 1.) used GOLD for the entire 2011-12 academic year, 2.) successfully completed an inter-rater reliability check conducted by Teaching Strategies, 3.) successfully completed all required face-to-face GOLD assessment training sessions, and 4.) successfully completed all online GOLD assessment training modules. These criteria helped insure that the teacher ratings came from users who understood how the tool was intended to be used to assess children's skills, knowledge, and behaviors. These criteria identified 81,375 children eligible for inclusion in the norm sample.

For this sub-population, children with complete data across three checkpoints were selected. Many programs record ratings for less than three checkpoints or do not follow a traditional academic year format. Typically programs require teachers to use an October due date for the fall checkpoint, a January due date for the winter checkpoint, and an April due date for the spring checkpoint. However, the exact assessment schedule can vary quite substantially across programs. Therefore, a window of acceptable due dates was set for each assessment checkpoint so that the resulting scores could be interpreted as representing a period of
approximately three months of growth and development between the checkpoints. Data recorded during September, October, and November was accepted for the fall checkpoint. Data recorded during December, January, and February was accepted for the winter checkpoint. Data recorded during March, April, May, and June was accepted for the spring checkpoint. In addition, the data for some individual children within programs that met these criteria were not complete for a variety of reasons. For example, a child may have joined late in the year, left the classroom before the end of the year, or had a large number of absences. These children were also excluded. Given all of these additional admissibility criteria, the resulting sub-population included ratings for a total of 69,743 children.

This sub-population did not represent the exact demographic distribution of children in the United States with respect to ethnicity and race according to the 2010 census. Therefore, a random sampling procedure was used to create a norm sample that reflected the most current estimates of the ethnic and racial diversity of the national population of children ages birth to five years of age. Table 1 contains the distribution of the norm sample across the seven commonly used racial and ethnic categories. Given that Hispanic refers to an ethnicity and not a racial designation, these categories are created by combining information about both the race and ethnicity of each child as reported by the teacher. The sampling procedure was successful in creating a norm sample that very closely approximated the national population. For example, the percentage of both African-American (13.6\%) and Hispanic (25.5\%) children matched the Census Bureau statistics. The four of the remaining five categories, White, Native-American, Pacific Islander, and Multiracial children, were all within .6 percentage points of the national statistics. Asian children were slightly under represented as they comprised $3.2 \%$ of the norm sample and $4.5 \%$ of the population.

Children were included from all regions of the United States, including 34 states, the District of Columbia, and Puerto Rico. The norm sample contains $51.3 \%$ boys and $48.7 \%$ girls. The primary language used in the homes of these children was English (77.5\%), Spanish (17.7\%), or other languages (4.8\%). Children with an Individual Education Plan (IEP) or an Individual Family Service Plan (IFSP) comprise 13.1\% of the sample. The total number of children included in the final norm sample was 54,504.

## Ratings of Child Growth and Development by Three Month Age Band

The norm sample was divided into three month age bands based on the age of each child at the time of the fall assessment checkpoint. The children were placed into eighteen three month age bands from 3 through 5 months to 54 through 56 months. The Teaching Strategies GOLD assessment system is designed to be used with children from birth to six years of age. However, there were very few children younger than 3 months of age or older than 56 months of age at the time of the fall assessment in the sub-population that were eligible for inclusion in the study and therefore these categories were not included in the norm sample.

Tables 2 through 7 include the mean and standard deviation for both the scale scores and raw scores for each of the domains of development that are included in the Teaching Strategies GOLD assessment system. The raw scores are created by summing across the teacher ratings for all the items within each domain of development. Each item is rated using a 10 point scale and the range of possible raw scores is as follows: Social Emotional (0-81), Physical (0-45), Oral Language (0-72), Cognitive (0-90), Literacy (0-108), and Mathematics (0-63). The total number of possible raw score points varies by domain of development because a different number of items is included in each scale.

The scale scores for each domain of development are based on Item Response Theory. They are interval level scale scores that result from a transformation of the raw scores, are not dependent upon the number of items rated for each domain, and are calibrated to have a mean of 500 and a standard deviation of 100 across the entire age range. The mean of 500 is associated with children at 36 months of age as this is the middle of the intended age range for the measure. Expected scores are reported for the Social Emotional (Table 2), Physical (Table 3), Oral Language (Table 4), Cognitive (Table 5), Literacy (Table 6), and Mathematics (Table 7) domains of development.

These tables are useful for researchers and teachers interested in fine grained examination of expected growth by narrow age bands. These tables show an overall trend indicating that the expected amount of growth tends to increase with age. These tables also illustrate that the child scale scores, as expected, tend to become a little more spread out as the children get older. The standard deviations for any given scale score tend to become larger as children get older.

## Reliability and Validity Evidence

A special case of the one parameter Item Response Theory model, the Rasch partial credit model, was used to examine the measurement properties of the item and scale scores for each of the developmental domains. These analyses were conducted to confirm, based on the current norm sample, the results of the Technical Manual for the Teaching Strategies GOLD Assessment System (Lambert, Kim, Taylor, \& McGee, 2010). These analyses were also used to establish that the process used to calibrate the interval level scale scores for each developmental domain was applicable to the current norm sample. The first step in this process was to examine the model assumption of unidimensionality, that each scale score is measuring only one underlying construct. This assumption is considered tenable if the model accounts for the
majority of the variance in item scores and the first contrast does not account for more than 5\% of the variance (Bond \& Fox, 2007). The results of the principal components analysis of residuals indicated that the model accounted for over $75 \%$ of the variance in the item scores for each of the six scale scores $(75.7 \%-84.3 \%)$. The first contrast accounted for $5 \%$ or less of the variance for all scale scores except the Physical domain which was very close to the criterion (6.0\%). These results taken together indicate that the assumption is tenable.

Next, fit statistics were examined to determine whether the item ratings fit the model. Infit (IMSE) and outfit (OMSE) mean square error statistics of . 6 to 1.4 are considered acceptable (Bond \& Fox, 2007). This criteria were met for every item on the Social Emotional (IMSE . 84 - 1.31, OMSE . 84 - 1.30), Physical (IMSE . 90 - 1.14, OMSE .90 - 1.13), Oral Language (IMSE . 83 - 1.30, OMSE .83 - 1.29), Cognitive (IMSE . 86 - 1.15, OMSE .86 - 1.16), and Mathematics (IMSE . $75-1.14$, OMSE $.75-1.12$ ) scales. These criteria were met for all but one item on the Literacy scale (IMSE . $76-1.52$, OMSE . 74 - 1.57). Therefore there is strong evidence that the data fits the model across all of the scales.

Item and person reliabilities and Cronbach's alpha reliabilities were examined for each scale score. Values greater than .80 are considered acceptable. Table 10 contains these coefficients, all of which are at or above 90 . Item and person separation indexes were also examined and values greater than or equal to 3 are considered acceptable, and as shown in Table 8, all of these values met this criterion.

## Kindergarten Entry Norms

A separate norm sample of kindergarten children was constructed. All children in the sample were at least 60 months old at the time of the fall assessment and were enrolled in a kindergarten classroom where the Teaching Strategies GOLD system was used as a fall
assessment. A total of 7,149 children met these criteria. This sub-population did not match the Census Bureau statistics for racial and ethnic composition. Therefore, a random sampling was used to match the national distribution as closely as possible. White children comprised $52.1 \%$ of the norm sample and $52.1 \%$ of young children nationally. African American children comprised $13.6 \%$ of the norm sample and $13.6 \%$ of young children nationally. Native American children were slightly overrepresented as they comprised $2.4 \%$ of the norm sample as compared to $.9 \%$ of young children nationally. Hawaiian and Pacific Islander children comprise $.3 \%$ of the norm sample and $.2 \%$ nationally. Multi-racial children were overrepresented as they comprise $6.1 \%$ or the norm sample and $3.2 \%$ of young children nationally. Hispanic children comprise $25.5 \%$ of the norm sample and $25.5 \%$ of young children nationally. Therefore, the norm sample formed a relatively nationally representative sample with the exception of over representing multiracial children and not including any Asian children (4.5\% nationally). The norm sample was $48.2 \%$ female and $51.6 \%$ male. Children with an IEP comprised $9.4 \%$ of the norm sample. English is the primary language spoken in the homes of $68.2 \%$ of the children as compared to Spanish (19.0\%) and other languages (12.8\%). A total of 4,155 were included in the final kindergarten norm sample.

Table 9 contains the means and standard deviations of each of the six scales for both the raw and scale scores. The expected scores for fall of the kindergarten year are generally higher than the winter assessments and lower than the spring scores in the norm tables for children who were 54-56 months of age at the time of the fall assessment. This makes sense as children who were 54-56 months of age at the time of their fall assessment in the four year old year would be 66-68 months of age during the fall assessment of their kindergarten year. This is a little older
than the children in this kindergarten sample as it is comprised of children who were generally 64-66 months of age at the time of the fall assessment.

## Conclusion

This report can serve as a companion to the technical manual (Lambert, Kim, Taylor, \& McGee, 2010). The results of this study demonstrate evidence for the reliability and validity of the scale scores created for each domain of development using the teacher ratings in this norm sample and confirm the results of the technical manual. These results also demonstrate that both the GOLD raw scores and scale scores for each domain of development are sensitive to the process of child growth and development. Teachers can use these results to understand how the scores of a particular child compare to a large, nationally representative norm sample. They can do so both at the beginning of the academic year, at kindergarten entry, and can compare the growth children are making across the academic year to the expected growth for children in the norm sample.
